Abstract. Background: Accumulating evidence has shown that hypoxia plays a key role in regulating proliferation of breast cancer cells. However, the mechanism of how hypoxia regulates breast cancer remains unclear. We sought to investigate if hypoxia regulated proliferation through circular RNA. Materials and Methods: Western blot was used to detect hypoxia-inducible factor 1 alpha (HIF1α) levels in breast cancer cells under hypoxic conditions. Candidate circular RNAs (circRNAs) were selected and quantified by quantitative real-time polymerase chain reaction (qRT-PCR) after hypoxia induction. CCK8 assay was used to investigate the changes of proliferation after interfering circDENND4C and HIF1α. Results: In breast cancer cells, circDENND4C was increased under hypoxic conditions and decreased after knocking-down HIF1α. In addition, knocking-down circDENND4C inhibited proliferation of breast cancer cells in a hypoxic environment. Finally, tumors with a large size had higher circDENND4C expression levels than those of small size. Conclusion: CircDENND4C is a HIF1α-associated circRNA promoting the proliferation of breast cancer cells under hypoxia.

Hypoxia is a key feature of most solid tumors and affects a variety of tumor cell properties, such as proliferation, angiogenesis, metastasis, metabolism and autophagy (1-5). To adapt to hypoxia stress, cancer cells respond by increasing the expression of hypoxia-inducible factor 1 alpha (HIF1α). HIF1α, which works as a transcription factor, extensively regulates transcriptions of coding genes, such as VEGF, IL-6, and non-coding genes, such as lncRNAs and miRNAs (6-8), that promote angiogenesis, proliferation and metastasis of cancer cells. Hypoxia level is reported to be positively correlated to prognosis of patients with cancer (9). However, the role of HIF1α in regulating some novel molecules, such as circular RNA (circRNA), remains unknown.

CircRNA is a novel type of RNA that forms a covalently closed continuous loop. CircRNAs were typically considered to be molecular flukes or byproducts of transcription. However, in recent years, a number of studies have indicated that circRNAs exhibited powerful functional potential in regulating proliferation and metastasis (10-12), suggesting that circRNAs may be important regulatory molecules in cancer. CircRNAs are very interesting in that, due to lack of 5’ cap and 3’ ends, they are not easily degraded by RNase R and are more stable than parent linear RNAs (13). Compared to HIF1α, HIF1α-associated circRNAs are, thus, more stable. In addition, circRNAs are abundant and conserved in mammalian cells, indicating circRNAs are ideal biomarker candidates for disease, including cancer, and several articles have identified certain circRNAs as biomarkers for predicting the prognosis of cancers, including esophageal, gastric and colon cancers (14-16). Therefore, identifying HIF1α-associated circRNAs with functional roles in cancer will have important clinical significance in translational medicine for biomarker-based clinical trials of cancer.

In the present study, we identified the existence of a hypoxia-associated circRNA, circDENND4C, in breast cancer cells and found that its expression was increased after hypoxia induction and decreased after knocking-down HIF1α. Knocking-down circDENND4C inhibited proliferation of breast cancer cells in a hypoxic environment. In addition, the clinical relevance between circDENND4C expression and clinicopathological features were also analyzed in human breast cancer samples. Our findings indicated that circDENND4C is an HIF1α-associated...
circRNA and its expression level is associated with the progress of the tumor and may be a substitutive biomarker for HIF1α in predicting the clinical impact of breast cancer.

Materials and Methods

Patients and tissue samples. Primary invasive ductal carcinomas of breast and adjacent non-cancerous breast tissues (referred to tissues more than 2 cm from tumors) were obtained from 30 female patients with breast cancer at the Breast Tumor Center, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, from January 2016 to April 2017. Patients were divided into several groups based on age (13 cases ≥50 years, 17 cases <50 years), tumor size (12 cases ≥5 cm, 18 cases <5 cm), lymph node (LN) status (16 cases with negative LN, 14 cases with positive LN), estrogen receptor (ER) status (17 cases for ER-positive, 13 cases for ER-negative), human epidermal growth factor receptor 2 (HER2) status (12 cases for HER2-positive, 18 cases for HER2-negative).

Cell lines, experimental conditions and treatment. MCF-7 and MDA-MB-231 cell lines were purchased from American Type Culture Collection (Manassas, VA, USA) and cultured according to the recommended protocols. Cells were subjected to hypoxia by placing in a CO₂ incubator and maintaining 20%, 10%, 1%, 0.2% O₂ by flushing nitrogen gas and 5% CO₂ at 37˚C in automatic intelligent anaerobic culture system (MART II, Amsterdam, the Netherlands) for every 12 h. For knock down the circDENND4C or HIF1α, specific siRNAs (Suzhou Jima Company, Suzhou City, China) were transfected with lipofectamine 3000 (Invitrogen, Carlsbad, CA, USA) into the cancer cells and 0.1 nmol siRNA was used for each well of 6-well culture plates.

CCK-8 kit assay. Four groups of MDA-MB-231 cells were divided into mock (transfected with only lipo3000), nc (transfected with lipo3000 and nc siRNA), si-1 and si-2 (transfected with lipo3000 and specific siRNA1 or siRNA2). Cells were cultured in 6-well plates and digested by 0.25% trypsin (Invitrogen) with siRNA transfection for 24 hours and added to 96-well plates with 100 μl of 3,000 cells. CCK-8 kits (Dojindo, Kumamoto, Japan) were used as inductions to evaluate the proliferation for four consecutive days and growth curves were drawn to show proliferation of cells dynamically. The first day’s data were not detected because cancer cells were not attached to culture plates.

RNA isolation and quantitative real-time polymerase chain reaction (PCR). Total RNA was isolated using the TR RNA isolation kit (Invitrogen) and RNA was reversely transcribed into cDNA with a reverse transcription kit (Promega, Madison, WI, USA). CircDENND4C and HIF1α were detected by quantitative real-time PCR using the following primer sequences: CircDENND4C forward, 5'-CCCTTTGTCTCTCTTAC-3' and reverse, 5'-ATAAGCGTTCCTTCCCTCCC-3', HIF1α forward, 5'-GAACGTCGAAAAGAATTACTG-3' and reverse, 5'-CCTTATCAAGATCGAATCTACA-3', β-actin forward, TCATGAAGTGTGACTTCATC and reverse, 5'-GAGGATGAGCAATCGACTC-3'. β-actin was included as an internal control and the relative expression level of circDENND4C and HIF1α were normalized to β-actin. The data were analyzed using the 2–∆∆Ct method, where Ct represents the threshold cycle number which each amplified product was initially detected. This method, together with the 2–∆∆Ct method, was used to calculate the relative changes seen in gene expression from the real-time quantitative PCR experiments.

Western blot analysis. Protein expression was detected by western blots as previously published (6). Antibodies against HIF1α were purchased from Abcam (Cambrige, England, UK) (Concentration 5 μg/ml, Cat. # GR194781-3) and antibody against β-actin was from Cell Signaling Technology (Danvers, MA, USA) (Concentration 1:1,000, Cat. # 20536-1-AP).

Statistical analysis. All statistical analyses were carried out using SPSS 16.0 (New York, NY, USA). All in vitro experiments were performed independently for at least three repeats. Analysis of variance (ANOVA) analysis was used to evaluate the differences of 4 groups in proliferation assays each day. Student’s t-test was used to evaluate the comparison of two independent groups in in vitro experiments or clinical subgroups. Linear regression analysis was used to analyze the correlation between expression of circDENND4C and HIF1α.

Results

HIF1α expression was up-regulated in breast cancer cells under hypoxia induction. Since HIF1α is the marker of the hypoxia process, we used western blotting to evaluate the

expression changes of HIF1α in MDA-MB-231 and MCF-7 cells under various oxygen concentrations (20%, 5%, 1%, 0.2% O2) after 24-h treatments. The degree of HIF1α in both MDA-MB-231 and MCF-7 cells increased when the O2 concentration was reduced (Figure 1). The results showed that HIF1α was a hypoxia-dependent protein in breast cancer cells with different molecular phenotypes. Because 0.2% O2 was the most effective concentration for hypoxia induction, we carried out our following experiments under 0.2% O2 concentration.

CircDENND4C is a HIF1α-associated circRNA under hypoxia induction in breast cancer cells. From published literature we found that circRNAs circZNF292, circAFF1, circTHSD1, circDENND4C, circSRSF4 and circFOXJ3 were reported previously as hypoxia-associated circRNAs in endothelial cells after hypoxia induction (17). Here, to identify hypoxia-associated circRNAs, we detected these six circRNAs in MDA-MB-231 cells after hypoxia induction using qRT-PCR. We found that circZNF292, circSRSF4 and circDENND4C were up-regulated as oxygen concentration decreased, while the other three circRNAs did not display significant change (Figure 2A-B). To further detect whether circZNF292, circSRSF4 and circDENND4C were affected by HIF1α, we knocked down HIF1α by specific siRNA in MDA-MB-231 cells in a hypoxic environment. Before subjecting the cells to hypoxia experiment, we confirmed that HIF1α-specific siRNAs successfully knocked down HIF1α at both mRNA and protein levels in MDA-MB-231 cells after hypoxia induction (Figure 2C-D). Compared to negative control groups, only circDENND4C expression was decreased after silencing HIF1α, while circZNF292 and circSRSF4 showed no obvious difference (Figure 2E). These results suggested that circDENND4C was a HIF1α-associated circRNA after hypoxia induction.

CircDENND4C mediates proliferation of breast cancer cells in hypoxic environment. Since hypoxia is an essential factor that affects proliferation in cancer (1, 10-12) and expression of circDENND4C was increased after hypoxia induction or decreased after knocking down HIF1α, we hypothesized that circDENND4C could mediate the proliferation of breast cancer cells. To explore the effect of circDENND4C on proliferation, we firstly used cell counting kit-8 to detect proliferation viability of MDA-MB-231 cells after silencing circDENND4C by two specific siRNAs, which were confirmed to silence circDENND4C (Figure 3A). We found that circDENND4C did not affect proliferation of cancer cells in normoxic conditions (Figure 3B). We went on to subject the cells to a hypoxia condition in that the oxygen concentration was 0.2% O2, as indicated earlier. We found that in this experimental setting, compared to the negative controls, silencing of either circDENND4C or HIF1α resulted in decreased proliferation of cancer cells (Figure 3C-D). These results indicated that circDENND4C manifested its function in regulating proliferation only in HIF1α-dependent-hypoxia but not normoxic environments.

CircDENND4C expression level is positively correlated to HIF1α level and tumor size in breast cancer patients. To further explore the clinical significance of circDENND4C in breast cancer patients, we firstly detected the expression level of circDENND4C in 30 paired cancer tissues and the adjacent normal tissues and found, by qRT-PCR, that tumor tissues highly expressed circDENND4C compared to the adjacent normal tissues (Figure 4A). Then, we detected the expressions of circDENND4C and HIF1α in 30 cases of breast cancer tissues, also by qRT-PCR, and analyzed their correlations. We found that the expression level of circDENND4C was positively correlated to HIF1α mRNA level (Figure 4B). Since our functional assay showed that circDENND4C affected the proliferation of cancer cells in vitro, we next analyzed the relationship between circDENND4C and clinicopathological features of breast cancer patients (Table I). We found that circDENND4C level was associated with tumor size (Table I & Figure 4C), while there was no significant correlation with the other clinicopathological features (Table I). All these clinical correlations were consistent with our finding in vitro and the already reported results that large tumors suffer more hypoxic damage than smaller ones (18). Our clinical analyses suggested that circDENND4C is a hypoxia-associated circular RNA and has a clinical impact on breast cancer patients.

Discussion

In the present study, our in vitro assays revealed that circDENND4C expression was increased after hypoxia induction and decreased after silencing HIF1α. Knocking-down circDENND4C inhibited proliferation of breast cancer cells in hypoxia environment. In clinical specimens of breast cancer, circDENND4C expression was more abundant in the tumor tissues than that of adjacent non-cancerous tissues and tumors with large size had increased circDENND4C expression level than those with small size. Our findings indicated that circDENND4C is a HIF1α-associated circRNA and its expression level is associated with the progression of tumor.

As increased cell proliferation of tumor promotes increased oxygen consumption (19-21), hypoxia is a feature of most solid tumors. To overcome hypoxic stress, cancer cells respond by increasing expression of HIF1α, a transcriptional factor in the nucleus responsible for transcription regulation of certain angiogenic and oncogenic factors. HIF1α is unstable in a normoxic environment and rapidly degrades through the ubiquitin-proteasome pathway;

by specific siRNAs. These preliminary data suggest that circDENND4C was decreased after knocking down treatment, while in all of these three circRNAs, only time in endothelial cells (17), and found that circZNF292, circSRSF4 and circFOXJ3, which were reported for the first time in human breast cancer, found that increased circDENND4C was associated with larger tumor size, rather than other indices, such as age, lymph node status, ER status and HER2 status. This clinical relevance suggests that circDENND4C might be a hypoxia-associated molecule having regulatory function in proliferation.

Hypoxia often occurs in the tumor environment, particularly in rapid growth of tumors and tumors of larger size. As a hallmark of hypoxia, HIF1α has been a biomarker in predicting the clinical relevance in cancer; however, its predictive performance in clinics is limited, partly due to its instability in both normoxic and hypoxic environments. In contrast, circRNAs are abundant, stable and tissue-specific. They are ideal characteristics for diagnostic and therapeutic biomarkers (13, 22-24). In our study, compared to the matched non-cancerous tissue, primary breast cancer tumors have higher circDENND4C levels, indicating that circDENND4C might be a cancer-specific circRNA. As neovascularization occurs around edges of tumors, internal parts of larger breast cancer tissues always suffer from severe hypoxia; smaller tumors suffer slightly because the total tissues absorb enough oxygen and nutritional materials (18-20). To some extent, the larger size of tumors sometimes means a faster proliferation. Therefore, tumor size can be an independent factor for hypoxia damage and results of proliferation. Indeed, we detected expression of circDENND4C in samples of human breast cancer and found that increased circDENND4C was associated with larger tumor size, rather than other indices, such as age, lymph node status, ER status and HER2 status. This clinical relevance suggests that circDENND4C might be a hypoxia-associated molecule having regulatory function in proliferation.

*The mean of circDENND4C expression was estimated using the 2−ΔΔCt method or by equation, power (2, - ΔCt). #Student’s t-test was used to analyze statistic differences in each subgroup. %Lymph node status: pN0 indicates no lymph node metastasis and pN1-3 indicates at least one lymph node metastasis. $ER status shows estrogen receptor expression in breast cancer. ER (+) means that at least 10% of breast cancer cells express ER detected by immunohistochemistry (IHC), while ER (-) demonstrates a percentage less than 10%. @HER2 status reveals expression of human epidermal growth factor receptor-2 in breast cancer. HER2 (+) denotes strong (+++) HER2 expression by IHC and/or HER2 overexpression by fluorescence in situ hybridization (FISH). HER2 (-) represents a weak (−++) or moderate (++) HER2 level as reported by IHC and no HER2 overexpression by FISH.
